

Misings and Unseen Values

- Missing Data in Training Predictors: Treated as a “level”
- Missing Value in Training Target: Ignored
- Unseen Categorical Levels During Scoring: Treated as an “NA” value and classified with outliers

# Pros/Cons of Decision Trees

- ✓ simple to understand/interpret
- ✓ little data prep
  - natural handling of “mixed” data types
  - handling of missing values
  - handling of multi-class outputs
- ✓ robustness to outliers in input space
- ✓ insensitive to monotonic transformations of inputs
- ✓ computational scalability (large N)  $\mathcal{O}(n \log n)$
- ✓ automatically ignores irrelevant inputs
- ✗ weak predictors
- ✗ can be unstable to small variations in the data
- ✗ poor ability to extract linear relationships
- ✗ can create biased trees if classes unbalanced

# Missing and Unseen Values

- Missing Data in Training Predictors: Treated as a “level”
- Missing Value in Training Target: Ignored
- Unseen Categorical Levels During Scoring: Treated as an “NA” value and classified with outliers
